#### **Abstract**

Although quality is not easy to evaluate since it is a complex concept compound by different aspects, several properties that make a good object-oriented design have been recognized and widely accepted by the software engineering community. We agree that both the traditional and the new object-oriented properties should be analyzed in assessing the quality of object-oriented design. However, we believe that it is necessary to pay special attention to the polymorphism concept and metric, since they should be considered one of the key concerns in determining the quality of an object-oriented system.

In this paper, we have given a rigorous definition of polymorphism. On top of this formalization we propose a metric that provides an objective and precise mechanism to detect and quantify dynamic polymorphism. The metric takes information coming from the first stages of the development process giving developers the opportunity to early evaluate and improve the quality of the software product. Finally, a first approach to the theoretical validation of the metric is presented.

## 1. Introduction

Object-oriented (O-O) software engineers need a better understanding of the desirable and non-desirable properties of O-O systems design, and their effect onto the quality factor. The desirable properties must represent those characteristics that ultimately lead to more efficient, reusable, maintainable and extensible software products.

The key issues related to the quality assessment of O-O systems are: firstly It is necessary to determine the desirable and non-desirable properties of systems, then there must be a formal definition of these properties. And finally, It is necessary to provide mechanisms to detect

(and quantify) the presence of these properties. These mechanisms must be formal and objective.

Although quality is not easy to evaluate since it is a complex concept integrated by different aspects, several properties that make a good O-O design have been recognized and widely accepted by the community. Despite the fact that the properties of coupling, cohesion, modularity, complexity and size, generally used to characterize quality in traditional structural design are also important in O-O designs, traditional metrics are not suitable for O-O designs. This problem is due to the presence of additional properties that are inherent to the O-O paradigm, such as abstraction, inheritance and polymorphism. These new concepts are vital for the construction of reusable, flexible and adaptable software products, and they must be taken into consideration by O-O software quality metrics.

The applicability problem of traditional techniques has been analyzed in the works of Chidamber and Kemerer [8], Tegarden et al. [21] and Wilde and Huitt [24] among others. Special metrics for O-O systems have also been investigated, for example the works of Chen and Lu [9], Kim et al. [12], and Li and Henry [15]. There are numerous proposals addressing the assessment of the traditional properties into O-O systems; for example the works of Poulin [19], Briand et al. [7], Price and Demurjian [20], Benlarbi [5]. But less work has been done in the field of the specific O-O properties; see for example the works of Moore [16], Bansiya ([2], [3], [4]), Benlarbi and Melo [6], Abreu and Carapuça [1], and Zuse [26].

An additional problem is that many of the currently available metrics can be applied only when the product is finished or almost finished, since data is often taken from the implementation stage. This makes the quality-weakness problems be detected too late. It is desirable to have a tool that takes information coming from the first stages of the

development process (i.e., requirement or analysis phases); this will give developers the opportunity to early evaluate and improve the quality of the product in the development process.

In this paper, new metrics to measure the quality of an O-O design are defined. These metrics are applied to the conceptual model of a system expressed in the Unified Modeling Language UML [22], thus permitting an early analysis of the system quality. Although we agree that both the traditional and the specific O-O properties or attributes should be analyzed in assessing the quality of O-O design, our purposes are not to define a complete quality evaluation mechanism (in the sense that it considers every system property), but only to characterize some aspects of the polymorphism attribute.

Polymorphism concept can be considered one of the key concerns in order to determine the quality of an O-O design. Regarding the literature [6] different kinds of polymorphisms have been classified, namely: pure, static, and dynamic ones. For instance, considering the latter, for two methods to be polymorphic, they need to have the same name and signature (parameter types and return type) and also the same effects (changing the state of the receiver in the same way and raising the same messages to other objects in the system). Dynamic binding lets one substitute objects that are polymorphic for each other at run-time. This substitutability is a key concept in O-O systems. Polymorphic systems have several advantages. They simplify the definition of clients, since as long as a client

only uses the polymorphic interface, it can substitute an instance of one class for another instance of a class that has the same interface at run-time. Because all instances behave the same way.

We formally define the polymorphism concept, giving foundations for its detection and quantification. Thus, the polymorphism measure should be combined with the measures of the rest of the properties (such as coupling, cohesion, entropy, etc.) with the aim of determining the total quality of the system. However, this metrics combination task is beyond the scope of this work.

## 2. The formal domain

We introduce the M&D-theory, a proposal for giving formal semantics to the Unified Modeling Language UML [22]. The basic idea behind this formalization is the definition of a semantic domain integrating both the model level and the data level. In this way, both static aspects and dynamic aspects of either the model or the modeled system, can be described within a first order formal framework.

The entities defined by the M&D-theory are classified in two disjoint sets: Modeling entities and Modeled entities. Figure 1 shows this dichotomy of entities. Modeling entities correspond to concrete syntax of the UML, such as Classes or StateMachine. In contrast, modeled entities, such as Object or Link represent run-time information, i.e. instances of classes and processes running on a concrete system.

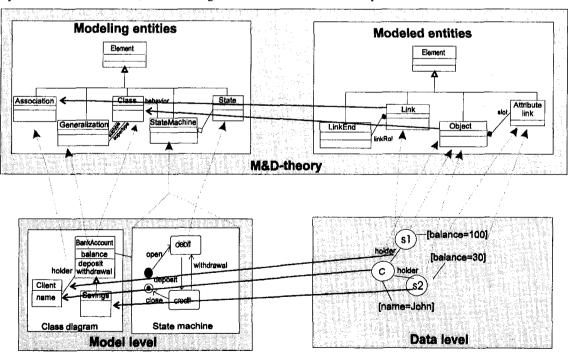

Figure 1: Dichotomy of metaentities in the M&D-theory

# 2.1. Structure of the theory

The M&D-theory is a first-order order-sorted dynamic logic theory<sup>1</sup> [11] [23], consisting of three sub-theories: M&D-theory= UML-theory + SYS-theory + JOINT-theory The language of the theory intentionally follows the UML metamodel [22].

## The sub theory UML-theory:

The theory describes modeling entities (i.e. models). In the UML, Class Diagrams model the structural aspects of the system. On the other hand, the dynamic part of the system is modeled by Sequence and Collaboration diagrams that describe the behavior of a group of instances in terms of message sendings, and by State Machines that show the intra-object dynamics in terms of state transitions.

Modeling entities are related to other modeling entities. Consider for example the association between Class and StateMachine by the relation labeled 'behavior'. This association indicates that StateMachines can be used for the definition of the behavior of the instances of a Class. Other example is given by the relation existing between StateMachine and State, that specifies that a StateMachine is composed by a set of States. It is important to formally define how the different UML diagrams are related to one another, in order to be able to maintain the consistency of the model. Moreover, it is important to specify the effect of modifications of these diagrams, showing what is the impact on other diagrams, if a modification is made to one diagram.

The theory consists of a signature  $\Sigma_{\text{UML}} = ((S_{\text{UML}}, \leq), F_{\text{UML}}, P_{\text{UML}}, A_{\text{UML}})$  and a formula  $\phi_{\text{UML}}$  over  $\Sigma_{\text{UML}}$ :

# $UML\text{-theory} = (\Sigma_{UML}\,,\,\varphi_{UML}\,)$

The set S<sub>UML</sub> contains sort symbols representing modeling elements, such as Class and StateMachine. The order relation between sorts allows for the hierarchical specification of the elements.

The sets of symbols  $F_{\text{UML}}$  and  $P_{\text{UML}}$  define functions and predicates over modeling entities.

The set  $A_{UML}$  consists of action symbols representing evolution of specifications over their life cycle. One of the most common forms of evolution involves structural changes such as the extension of an existing specification by addition of new classes of objects or the addition of

attributes to the original classes of objects. At the other extreme, evolution at this level might reflect not only structural changes but also behavioral changes of the specified objects. Behavioral changes are reflected for example in the modification of sequence diagrams.

The formula  $\phi_{UML}$  is the conjunction of two disjoint sets of formulas,  $\phi_S$  and  $\phi_D$  of static and dynamic formulas respectively. The former consists of first-order formulas which have to be valid in every state the system goes through (they are invariants or static properties or well-formedness rules of models). These rules are used to perform schema analysis and to report possible schema design errors. The latter consists of modal formulas defining the semantics of actions, that is to say, the evolution of models.

## The sub theory SYS-theory:

This theory describes the modeled entities (i.e. data and process). The elements in the data level are basically instances (data value and objects) and messages. At the data level a system is viewed as a set of related objects collaborating concurrently. Objects communicate each other through messages that are stored in semi-public places called mailboxes. Each object has a mailbox where other objects can leave messages.

Modeled entities are related to other modeled entities. For example the relationship named 'slot' between Object and AttributeLink, denotes the connection between an Object and the values of its attributes.

The theory consists of a signature  $\Sigma_{SYS}$ = (( $S_{SYS}$ ,  $F_{SYS}$ ,  $P_{SYS}$ ,  $A_{SYS}$ ) and a formula  $\gamma_{SYS}$  over  $\Sigma_{SYS}$ :

SYS-theory =  $(\Sigma_{SYS}, \gamma_{SYS})$ 

The set  $S_{SYS}$  contains sort symbols representing the data in the system and its relationships, such as objects, links, messages, etc.

The sets of symbols  $F_{SYS}$  and  $P_{SYS}$  define functions and predicates over data. The set  $A_{SYS}$  consists of action symbols representing evolution of data at run time, such as object state changes.

The formula  $\gamma_{SYS}$  is the conjunction of two disjoint sets of formulas,  $\gamma_S$  and  $\gamma_D$  of static and dynamic formulas respectively. The former consists of first-order formulas which have to be valid in every state the system goes through (they are invariants or static properties or well-formedness rules of data). Whereas, the latter consists of modal formulas defining the semantics of actions, that is to say the possible evolution of the data.

# The sub theory JOINT-theory:

This part of the theory describes the connection between model and data levels. Modeling entities are related to modeled entities. There is a special relationship among some modeled entities with their corresponding

<sup>&</sup>lt;sup>1</sup> A first-order order-sorted dynamic logic theory  $Th = (\Sigma, \phi)$  consists of a signature  $\Sigma$  that defines the language of the theory, and a set  $\phi$  of  $\Sigma$ -axiomas .A signature  $\Sigma = ((S, \leq), F, P, A)$  consists of a a set of sort symbols S, a partial order relation between sorts  $\leq$ , function symbols F, predicate symbols P, and Action symbols A.

modeling entity, This relationship denotes 'instantiation', for example an Object is an instance of a Class, whereas Links are instances of Associations.

Finally,  $\phi_{\text{JOINT}}$  is a formula constructed over the extended language  $\Sigma_{M\&D}$ , and thus it can express at the same time data properties (e.g. behavioral properties of objects), model properties (e.g. properties about the system specification), and properties relating both aspects. Details of the theory can be found in [29], [30] and [31].

## 2.2. Advantages of the integration

The integration of modeling entities and modeled entities into a single formalism allows us to express both static and dynamic aspects of either the model or the modeled system within a first order framework. The validity problem (i.e. given a sentence  $\phi$  of the logic, to decide whether  $\phi$  is valid) is less complex for first-order formalisms than for higher order formalisms. Although first order logic is undecidable, computer systems satisfy certain properties (e.g. systems are interpreted over arithmetic structures, the state of a program is given by a finite set of values) that allow us to calculate the validity of formulas in an effective way.

The integrated formalism is suitable for the definition of a variety of properties of O-O systems, structural properties as well as behavioral properties.

The logic allows us to define structural properties such as: depth of class hierarchy, size of class interface, number and type of associations between classes, etc. These properties can be expressed because classes, associations, generalization, etc. are first-class citizens in the logic. On the other hand, instances and their behavior are also first-class citizens of the logic, as a consequence, it is possible to define behavioral properties such as pre/post conditions of operations, equivalence of behavior, among others.

# 2.3. Using the M&D-theory to formalize an O-O model

We formally define the semantics of the UML using a two-step approach:

- 1- interpretation (or translation) of the UML to the M&D-theory.

2- semantics interpretation of the M&D-theory.

That is to say, UML-constructions → translation M&Dtheory > semantics Semantics-domain

The semantics mapping Sem is the composition of both functions, Sem=semantics o translation

The first step converts an UML model instance to the modal logic theory; the conversion provides a set of formulas that serves as an intermediate description for the

meaning of the UML model instance. The key components of this step are rules for mapping the graphic notation onto the formal kernel model.

The second step is the formal interpretation of this set of formulas. The semantics domain where dynamic logic formulas are interpreted is the set of transition systems. A transition system,  $U=(S^U, w_0, m_U)$ , is a set of possible worlds or states with a set of transition relations on worlds. For details about semantics of dynamic logic, see [11] and [23]. Formally, let  $\Sigma$ =( (S,  $\leq$ ), F, P, A) be a first-order dynamic logic signature and let  $\Sigma_N$ =( (S,  $\leq$ ),  $F_N$ ,  $P_N$ ) be the nonupdatable part of  $\Sigma$ . Let  $U=(A,m_U)$  be a  $\Sigma_{N}$ -algebra, providing a domain for the interpretation of static terms. Formulas of the language are interpreted on Kripke-frames as follows:  $U=(S^U, w_o, m_U)$ . Where:

- ✓  $S^U$  is the set of states. Each state  $w \in S^U$ , is a function that maps terms to the algebra U.
- $\checkmark$  w<sub>0</sub>∈ S<sup>U</sup> is the initial state.
- $\checkmark$   $m_{\rm U}$  associates each action  $\alpha$  to a binary relation called the input/output relation of  $\alpha$ :  $m_U(\alpha) \subseteq S^U \times S^U$

The domain for states is an heterogeneous  $\Sigma_{N}$ -algebra whose elements are both model elements (such as classes) and data elements (such as objects).

The interpretation of a term t in a state w given v (written as intw(t)) is defined in the usual way. The satisfaction of a closed formula in a structure U and a state w is defined as follows:

```
U,w \models (t1=t2) \text{ iff } int_w(t1)=int_w(t2)
U,w \models \neg \phi \text{ iff } not(U,w \models \phi)
U,w \models \phi \land \gamma \text{ iff } U,w \models \phi \text{ and } U,w \models \gamma
U,w \models [a]\phi \text{ iff } \forall w', \text{ if } (w,w')\in m_U(\alpha), \text{ then } U,w'\models \phi.
```

A model for a specification  $sp=(S,F,P,A,\phi)$  is a structure U such that  $U, w_0 = \phi$ .

## 3. Formal Definition of Polymorphism

In this section, we give a rigorous definition of polymorphism in the framework of the M&D-theory. Main definitions of the polymorphism concept can be read in [25]. Let M be an UML model of an O-O system. Let U be the formal semantics of that model, i.e. U = Sem(M).

## **Definition 1: Polymorphic Methods**

For two methods to be polymorphic, they need to have the same name and signature (parameter types and return type) and also the same effects (changing the state of the receiver in the same way and raising the same messages to other objects in the system).

Let m be a method name. Let  $C_1$  and  $C_2$  be two classes existing in the model M.

The methods named m are polymorphic in  $C_1$  and  $C_2$  in the model U if the following formula holds:

 $U \models Polymorphic(m,C_1,C_2)$ 

Where the predicate Polymorphic is defined as follows:

## Def 1.1:

 $\forall m: Name \ \forall C_1, C_2: Class \bullet$   $Polymorphic(m, C_1, C_2) \leftrightarrow$   $\exists m_1, m_2 \bullet (m_1 \in C_1. operations \land m_2 \in C_2. operations \land m_1. name=m \land m_2. name=m \land m_1. visibility=m_2. visibility <math>\land hasSameSignature(m_1, m_2) \land hasSameBehavior(m, C_1, C_2))$ 

The predicate hasSameSignature applied on two methods is true if both methods have the same signature. It is defined in the M&D-theory as follows:

#### Def 1.2:

∀b,b':BehavioralFeatures • hasSameSignature(b,b') ↔ (b.name= b'.name ∧ areEquivalent(b.parameters, b'.parameters))

Where are Equivalent is defined as follows:

## Def 1.3:

 $\begin{tabular}{ll} $\operatorname{areEquivalent}(\lambda,\lambda)=\operatorname{true} \\ $\operatorname{areEquivalent}(p:ps,\,\lambda)=\operatorname{false} \\ $\operatorname{areEquivalent}(\lambda,p:ps)=\operatorname{false} \\ $\operatorname{areEquivalent}(p_1:ps,p_2:ps^{\ })= \\ &\operatorname{equivalent}(p_1,p_2) \wedge \operatorname{areEquivalent}(ps,ps^{\ }) \\ \end{tabular}$ 

Where  $\lambda$  denotes the empty sequence and p:ps denotes a non-empty sequence made up from a head (denoted by p) and a tail (denoted by ps).

And finally, the predicate equivalent is applied on two single parameters determining their equivalence.

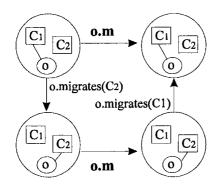

Figure 2: commutartivity of polymorphic mehods

## Def 1.4:

 $\forall p_1, p_2: Parameter \bullet equivalent(p_1, p_2) \leftrightarrow (p_1.defaultValue=p_2.defaultValue \land p_1.kind=p_2.kind \land p_1.type=p_2.type)$ 

Two methods named m have the same behavior in  $C_1$  and  $C_2$  if they are indistinguishable (see figure 2), i.e., for every two objects  $o_1$  and  $o_2$  (being  $o_1$  instance of  $C_1$  and  $o_2$  instance of  $C_2$ ), the effect of executing o.m is the same as the effect of executing o.m, where o.m denotes that object o receives and execute the method named m. The predicate is defined as follows:

## Def 1.5:

```
U,w |= hasSameBehavior(m,C<sub>1</sub>,C<sub>2</sub>) iff

∀o:Object • o.classifier=C<sub>1</sub> then

∀w<sub>1</sub> • (w,w<sub>1</sub>) ∈ m_U(o.m) then

∃ w',w'<sub>1</sub> • ((w,w') ∈ m_U(o.m)grates(C<sub>2</sub>))

∧ (w',w'<sub>1</sub>) ∈ m_U(o.m)

∧ (w'<sub>1</sub>,w<sub>1</sub>) ∈ m_U(o.m)grates(C<sub>1</sub>)))
```

That is to say, the diagram in figure 2 commutes, where the action o.migrates(C) represents that object o switches its class to C (see definition 1.6).

## Def 1.6: [o.migrates(C)] o.classifier=C

<u>Corollary</u>: for every formula  $\phi$ , the following schema is valid in the class of models satisfying that the method named m is polymorphic in classes  $C_1$  and  $C_2$ :

 $\forall o \in instances(C_1) \quad [o.m] \varphi \quad \longleftrightarrow \quad [o.migrates(C_2)] \quad [o.m] \\ [o.migrates(C_1)] \ \varphi$ 

# **Definition 2: Polymorphic Classes**

Two classes are polymorphic if they define the same methods, and these methods are polymorphic. Two objects belonging to polymorphic classes are polymorphic objects. Dynamic binding lets us substitute objects that are polymorphic for each other at run-time. This substitutability is a key concept in O-O systems.

Formally, two classes  $C_1$  and  $C_2$  are polymorphic in model U, if the following condition holds:

 $U \models Polymorphic(C_1, C_2)$ 

Where the predicate Polymorphic is defined in the following way:

#### Def 2.1:

```
\forall C_1, C_2: Class • Polymorphic(C_1, C_2) \leftrightarrow
interface(C_1)=interface(C_2) \land
\forall n \in interface(C_1) • polymorphic<math>(n, C_1, C_2)
```

Function interface returns the set of names of public methods of a class. It is defined in the following way:

## Def 2.2:

```
\forallC:Class • \foralla:Name • (n∈interface(C) \leftrightarrow \existsf∈ C.allFeatures • (f.name=n \land f.visibility=#public))
```

# **Definition 3: Polymorphic Hierarchy**

The concept of polymorphic class as previously defined is too strong, because in general only some of the methods of a class are polymorphic, not all of them. Therefore, a more flexible concept of polymorphism has been defined (see [25]), named *core interface*. A *core interface* is a set of polymorphic methods that several classes share. For a hierarchy to be polymorphic all its classes must share a core interface.

Polymorphic hierarchies have several advantages. They simplifies the definition of clients, since as long as a client only uses the core interface, it can substitute an instance of one class for other instance of a class that has the same core interface at run-time. Because all of instances behave the same, one works just as well as another, with regard to the core interface.

Formally, let H be a set of classes in an O-O hierarchy. Hierarchy H is polymorphic in the model U if there exists a *core class* (this core class might not belong to the set H). The formula below defines the concept of polymorphic hierarchy: U = Polymorphic(H)

Where the predicate Polymorphic is defined in the following way:

## Def 3.1:

```
\forallH:Set of Class • ( Polymorphic(H) \leftrightarrow \existsC:Class • isCore(C,H) )
```

Where isCore is defined as follows:

## Def 3.2:

```
\forall H:Set of Class • \forallC:Class • ( isCore(C,H) \leftrightarrow (interface(C)\neqØ \land \forallS \in H • ( interface(C)\subseteqinterface(S) \land \foralln \in interface(C) • polymorphic(n,C,S) ) ) )
```

The degree of polymorphism depends on the size of the core interface. The larger the core is, the higher the polymorphism degree is.

# 4. The Polymorphism metric

In the previous sections, we have given a rigorous definition of polymorphism in the framework of the M&D-theory [17] [18]. On top of this formalization we propose a metric for measuring polymorphism, that provides an

objective and precise mechanism to detect and quantify polymorphism.

We define the following functions on O-O UML models.

Let S be a UML Model, that is to say, a Package containing a hierarchy of modelElements that together describe an abstraction of a physical system.

 hierarchies(S) returns a collection containing every non trivial, pair-wise disjoint hierarchy defined in S.

Then, we define the following functions on a class hierarchy h (we restrict h to be a tree):

- classes(h) returns a set containing all of the classes.
- methods(h) returns a bag containing all of the methods defined in the hierarchy, as follows:
- ♦  $methods(h) = \bigoplus_{c \in classes(h)} interface(c)$ , where  $\bigoplus$  represents bags union(with repetitions).
- ♦ core(h) returns the largest core in the hierarchy h.
- width(h) returns the width of the hierarchy, it is defined as follows:
  - width(h) = #(interface(core(h))) , where the symbol #
    denotes set cardinality.
- children(h) returns the set of direct sub-hierarchies of hierarchy h.

Let S be an UML model, the polymorphism metric of S is the average polymorphism measure of every pairwise disjoint hierarchies in S. The polymorphism metric function is defined as follows:

```
\begin{array}{l} polymorph\_metric : System \rightarrow \{0..1] \\ polymorph\_metric(S) = \sum_{h \in hierarchies(S)} polymorph\_measure(h) \end{array}
```

#hierarchies(S)

polymorph\_measure: Hierarchy  $\rightarrow$  [0..1]

## Trivial Case:

if #classes(h)=1 then polymorph\_measure(h)=0

## General Case:

```
if #classes(h)>1 then
polymorph_measure(h)=polymorphic_methods(h)
```

#methods(h)

## Where:

 $\begin{aligned} & polymorphic-methods(h) = width(h) * \#classes(h) + \\ & \sum_{h \in children(h)} polymorphic-methods(hi - core(h)) \end{aligned}$ 

Where (hi - core(h)) stands for the hierarchy resulting after removing from hi all of the methods belonging to core(h). Let us remark that the result of the function polymorph\_metric is in the interval [0...1], where the number zero represents the absence of polymorphism, while the number 1 represents the highest degree of

polymorphism (i.e., all of the methods in the hierarchy are polymorphic). In the case of trivial hierarchies (i.e., hierarchies made up from a single class), the metrics returns zero.

# 5. Examples

In this section, the polymorphism metric is applied to a hierarchy of Collection.

# 5.1. Identifying polymorphism

The hierarchy of collections has been defined and implemented in numerous O-O languages. Figure 3, shows a part of the Collection hierarchy of Smalltalk[14]. Using the formal definitions of the M&D-theory we can identify the presence of polymorphic methods in this hierarchy, for example: size, includes:, select:, remove:, add:, etc. In the Figure 3 every polymorphic method appears only once in the hierarchy of classes. For example, every class of the hierarchy has a polymorphic method named select:. Instead of including the method in each class, we only include it once in the root of the hierarchy.

As an example, we show the formal proof of that the method named remove: is polymorphic for classes Set and Bag. The statement aCollection.remove:anElement denotes that the element equal to anElement is removed from the receiver collection. In the case the receiver is a Set, at most one occurrence can belong to the set, but in the case the receiver is a Bag, several occurrences of the same object may belong to it. In the same way, it is possible to proof that method add: is not polymorphic for classes Set and Bag (i.e.  $\mid$  = ¬Polymorphic(add:, Set, Bag)) due to the detection of duplicated elements.

Classes	<b>Public Instance Methods</b>
Collection	size, includes:, select:, collect:, reject:, detect:
NotIndexedCollection	remove:
Set	add:
Bag	add:
IndexedCollection	last, first, at:, at:put:
FixedSizeCollection	
Array	
String	<,>
VariableSizeCollection	remove:
OrderedCollection	add:
SortedCollection	add:

Figure 3: part of the Collection hierarchy

Theorem 1: remove is polymorphic for classes Set and Bag: = Polymorphic(remove, Set, Bag)

<u>Hypothesis</u>: Let Set and Bag the classes in the Smalltalk hierarchy. There exists an operations removeSet belonging to Set.interface, and there exists an operation removeBag belonging to Bag.interface, such that:

[h0] removeSet∈ Set.interface \( \) removeBag∈ Bag.interface

[h1] removeSet.name=remove^removeSet.visibility=public

[h2] removeSet.parameters= <p1>

[h3] p1.defaultValue=nullElement

[h4] p1.kind=in \( p1.type=Object \)

The specification of the operation is given by the following dynamic logic formula:

[h5]  $\forall$ s,e:Object • (s.classifier=Set  $\rightarrow$  [s.remove(e)]e $\notin$ s)

[h6] removeBag.name=remove \( \)

removeBag.visibility=public

[h7] removeBag.parameters= <p2>

[h8] p2.defaultValue= nullElement

[h9]  $p2.kind = in \land p2.type=Object$ 

The specification of the operation is given by the following dynamic logic formula:

[h10] ∀b,e:Object (b.classifier=Bag ∧

occurrences(b,e)= $n \rightarrow [b.remove(e)]$ occurrences(b,e)=n-1)

We need first to prove the following lemmas:

**<u>Lemma 1</u>**: both operations have the same signature:

= hasSameSignature(removeSet,removeBag)

<u>Lemma 2</u>: the method *remove*: has the same behavior in both classes:

|= hasSameBehavior(remove, Set, Bag) \\
hasSameBehavior(remove, Bag, Set)

<u>Proof of lemma 2</u>: We have to prove that the corollary holds. Since this dynamic logic has a minimal change semantics, only it is necessary to analyze the post-conditions of the method remove, because no other change is allowed to happen. That is to say, the instance of the corollary we have to prove is:

 $\forall s \in Set.instances \bullet \forall e:Object \bullet [s.remove(e)] e \notin s \leftrightarrow [s.migrates(Bag)] [s.remove(e)] [s.migrates(Set)] e \notin s$ 

∧ ∀b∈ Bag.instances ∀e:Object •

[b.remove(e)] occurrences(b,e)=n-1↔[b.migrates(Set)] [b.remove(e)] [b.migrates(Bag)] occurrences(b,e)=n-1

Where n is equal to occurrences(b,e) before the removing. The complete proof can be read in [18].

## Proof of the theorem:

Now we can prove the theorem, as follows:

[t1]  $\exists m_1, m_2 \bullet (m_1 \in Set.operations \land m_2 \in Bag.operations$ 

 $\land$  m<sub>1</sub>.name= remov  $\land$  m<sub>2</sub>.name= remove

^ m<sub>1</sub>.visibility=m<sub>2</sub>. visibility ^hasSameSignature(m<sub>1</sub>,m<sub>2</sub>) ^ hasSameBehavior(remove,Set,Bag) ) Finally the theorem is proved applying modus ponens to

Finally the theorem is proved applying modus ponens to def. 1.1 and [t1].

# 5.2. Applying the metric

The polymorphism metric is applied to the Smalltalk Collection hierarchy in Figure 3. In that figure polymorphic methods have been previously detected (using the definitions of section 3) and moved up in the hierarchy (i.e. the root class of the hierarchy is also the largest core class in the hierarchy). Methods appearing twice (or more times) in the hierarchy actually are non-polymorphic methods, for example, the method add: is non-polymorphic for Set and Bag.

Measuring Polymorhism to the Collection hierarchy:  $polymorph_measure(h_C) = polymorphic_methods(h_C) /$ #methods(h<sub>C</sub>) = polymorphic\_methods(h<sub>C</sub>) / 106 (because  $\#methods(h_C) = 106$ ) = (width( $h_C$ ) \* #classes( $h_C$ ) +  $\sum_{hi \in children(}h_{C)}$  polymorphic $methods(h_i - core(h_C))) / 106$ (from definition of polymorphic\_methods(h<sub>C</sub>)) =  $(6 * 11 + \sum_{h \in children(h_C)} polymorphic-methods(h_i$  $core(h_C)$ ) /106 (because width( $h_C$ )=6, #(classes( $h_C$ )=11) + polymorphic-methods(sub-hierarchy-( 66 polymorphic-methods(sub-NotIndexedCollection) + hierarchy-IndexedCollection) / 106 = (66 + 3 + 31) / 106 = 0.94 (or 94 %)

 $\label{eq:value to the IndexedCollection sub-hierarchy (hX):} $$ \text{polymorphic\_methods}(h_X) = ( \text{width}(h_X) * \#\text{classes}(h_X) + \sum_{hie\,\text{children}}(h_X) \, \text{polymorphic-methods}(h_i - \text{core}(h_X)) ) = (4 * 7 + \sum_{hie\,\text{children}}(h_X) \, \text{polymorphic-methods}(\text{sub-hierarchy-rivedSizeCollection}) + \text{polymorphic-methods}(\text{sub-hierarchy-polymorphic-methods}(\text{sub-hierarch$ 

<u>Value to the VariableSizeCollection sub-hierarchy (hV):</u>
polymorphic\_methods( $h_V$ ) = (width( $h_V$ ) \* #classes( $h_V$ ) +  $\sum_{hi \in children}(h_V)$  polymorphic-methods( $h_i$  - core( $h_V$ ))) = 3

hierarchy-VariableSizeCollection) = (28 + 0 + 3) = 31

It can be observed in the outcome, the high degree of polymorphism of the Collection hierarchy (reaching the value of 94 %), which contributes potentially to the readability, extensibility, and ultimately to their maintainability. However, some studies, that should further be confirmed, indicate that polymorphism may increase the probability of faults in O-O software –see for example [6].

# 6. Towards a Validation of the Metric

(from lemma 1, lemma2, [h0], [h1] and [h7])

There are two strategies to corroborate or falsify the validity of metrics: the *theoretical* and the *empirical* validation. The theoretical validation is mainly based on mathematical proofs that allows us to formally confirm that the measure does not violate the properties of the empirical systems, the definition models and criteria. On the other hand, the empirical validation consists on the realization of experiments and observations on the real world in order to corroborate or falsify the metric.

In addition, validation approaches can be classified according to the class of attribute that is taken into consideration. From this point of view a metric is valid internally or "valid in the narrow sense" [10], if it analyses properties that are inherent of the system, while a metric is valid externally or "valid in the wide sense" if it considers higher level characteristics (e.g., cost, quality, maintainability, etc.) mainly for prediction purposes. Finally, some metrics can be measured directly (such as the number of classes or methods of a class hierarchy), while others can only be measured indirectly by means of an equation or model.

In this section, we will analyze aspects of the theoretical validation for the polymorphism metrics discussed and exemplified in sections 4 and 5. These metrics consider internal attributes of a product entity, e.g., an O-O design specification of a software system. In a general sense, the Kitchenham's assumption [13] is that in order for a measure to be valid these two conditions must be held: 1) the measure must not violate any necessary property of its elements; 2) each model used in the process must be valid. The structural framework of Kitchenham et at. [13] can be combined with the axiomatic framework of Zuse [26] to yield a wider conceptual framework (Olsina et al., 2000). Regarding the proposed conceptual framework in order to decide whether a metric is valid, it is necessary at least to check:

✓ Attribute validity, i.e., whether the attribute is actually exhibited by the entity being measured. For a given attribute, there is always at least an empirical relationship of interest that can be captured and represented in the numerical domain, enabling us to explore the relationship analytically. This can imply a theoretical and/or empirical validation.

✓ Unit and Scale Type validity, i.e., whether the measurement unit and scale type being used are an appropriate means of quantifying the internal or external attribute. When we measure a specific attribute of a particular entity, we consider a scale type and unit in order to obtain magnitudes of type value. Thus, the measured value can not be interpreted unless we know to what entity is applied, to what attribute is measured and in what unit is

expressed (i.e., the empirical and numeric relational systems should be clearly specified). On the other hand, a scale type is defined by admissible transformations of measures.

✓ Instrument validity, i.e., whether any model underlying a measuring instrument is valid and the same one is properly calibrated. In order to obtain the measured value we can do it either manually or automatically by using partial or totally a measurement instrument (a software tool).

✓ Protocol validity, i.e., whether an acceptable measurement protocol has been used in order to guarantee repeatability and reproducibility in the measurement process.

Regarding the polymorphism metric, some empirical considerations should be made. As aforementioned, the hierarchies(S) function returns the collection containing all the non-trivial disjoint hierarchies defined in S. This guarantees, for example, that the intersection between two hierarchies gives the empty set. In addition, we are only considering tree hierarchies which allow us to model single inheritance (Java and Smalltalk languages, among others, only support single inheritance). In order to try guarantee the ratio scale for the polymorphism\_measure metric, we

started to investigate the modified extensive structure and the additive properties discussed in [26]. However, the initial results draw that the metric does not accomplish the independence condition C1, and the axiom of weak monotonicity. So, for that metric the absolute scale has in principle been validated as follows:

<u>Theorem 6.1</u>: The scale type of the metric is absolute. <u>Proof</u>: Let m = A/B be the metric, and let A, B be absolute

values (1)
Where A represents the polymorphic\_measure attribute;

Where A represents the *polymorphic\_measure* attribute; and B represents the total number of methods of a hierarchy (#methods(h)). It is always satisfied that  $A \le B$ , and therefore it holds that  $A \subseteq B$ . The relationship between A and B can be described by:

A = c B; with c>0. (2)

Replacing (1) in (2), the following equation is obtained: m = c B/B = c.

The resulting m is an absolute scale. Percentage measures can be used as an absolute scale, but they do not assume an extensive structure (see [26] pp. 237-238). Figure 4 shows descriptions of the theoretical validity for a set of used functions for the metric.

Attribute	Scale Type	Unit	Criteria and Properties that Apply
#classes(h)	Absolute	Number of classes in h	These internal attributes are exhibited in O-O design and implementation specifications. They are simply direct
#methods(h)		Total number of methods in h (regarding bags)	metrics.  Different hierarchy specifications may have different number of classes, methods, etc. for the respective
width(h)		Number of polymorphic methods (to h)	attribute. Conversely, different hierarchy specifications may have the same number of classes, methods, etc.  ✓ They fulfill the representation condition  ✓ The unit and scale type are defined and confirmed.
#hierarchies (S)		Number of hierarchies in the S specification	Accordingly, they are obtained by counting elements where an absolute scale is generally implied (but not always). The only possible transformation is the identity.
Polymorphi c_methods.	Absolute	(Number of polymorphic methods * Number of classes)	✓ It is an indirect metric. The equation is shown in Section 4. ✓ The unit and scale type are defined. It yields an absolute scale.
Polymorph_ measure.	Absolute	[(Number of polymorphic methods * Number of classes) / Total number of methods to h], It represents the percentage of polymorphic methods of a hierarchy	✓ It is an indirect metric. The equation is shown in Section 4.  ✓ It fulfills the representation condition (That is, greater number of polymorphic methods with regard to the total amount of methods of a hierarchy leads to a higher degree of polymorphism –hence, the specification can be more understandable, reusable and extensible). The absence of polymorphic methods in a hierarchy yields a zero value. Conversely, the 1 value (or 100%) means that all methods are polymorphic.  ✓ The unit and scale type are defined. It yields an absolute scale as demonstrated by the theorem 6.1.

Figure 4: Descriptions of theoretical validity for the polymorphism metric and its elements

The target entity is an O-O design specification or a source code of an O-O program. The instrument validity is applicable because data collection and calculations can be carried out automatically. The main algorithm is supported by the recursive model. Ultimately, the measure of polymorphism of a set of disjoint hierarchies defined in the S specification is computed by making an average as shown in Section 4. This statistical analysis is allowed to magnitudes of an absolute scale type.

# 7. Concluding Remarks

Although quality is not easy to evaluate since it is a complex concept compound by different aspects, several properties that make a good O-O design have been recognized and widely accepted by the software engineering community. We agree that both the traditional and the new O-O properties or attributes should be analyzed in assessing the quality of O-O design. But we believe that it is necessary to pay special attention to the concepts and metrics for *polymorphism*, since it should be considered one of the key concerns in determining the quality of an O-O software system.

In this paper, we have given a rigorous definition of polymorphism in the framework of the M&D-theory [17] [18]. Besides, on top of this formalization we propose a metric for measuring polymorphism, that provides an objective and precise mechanism to detect and quantify dynamic polymorphism. It is proven that the metric is valid regarding a theoretical validation framework. Furthermore, it is important to remark that the metric takes information coming from the first stages of the development lifecycle giving developers the opportunity to early evaluate and improve the quality of the software product.
